New Jersey Agricultural
Experiment Station

Food Waste: Case Studies and Modeling

Donald W Schaffner, PhD

Distinguished Professor and Extension Specialist

Overview

- Summary of four case studies
 - Milk
 - Potatoes
 - Bananas
 - Bread
- Modeling tools
 - Chicken

Milk – safe after boiling

- 8 log CFU/ml at 14-17 days spoiled by *Pseudomonas*
 - Some strains may cause diarrhea in immunodeficient individuals
- 4 log CFU/ml at 14 days spoiled by *Paenibacillus*
 - Species appears to lack many virulence genes and toxins common in *B. cereus*
- 6 log CFU/ml at 17 days spoiled by *Bacillus*
 - Strains that produce toxin unable to grow at temperatures less than 10 °C

Potatoes

- Poisonings from glycoalkaloids can occur
 - relatively rare in recent history
- Bitter taste can be associated with glycoalkaloid poisoning
- Toxicological limits have not been set
 - levels of less than 100mg/kg potatoes do not appear to be of concern
- Sprouting and green color have been associated with elevated glycoalkaloids
 - green color itself is not a specific marker for glycoalkaloids
- Old potatoes ok if sprouts, green color, skin, and peels plus the area under skin are discarded
- Cooked old potatoes which taste bitter should not be consumed

Bananas

- Risks of bacterial disease from bananas appear to be very low
 - based on CDC data and limited published data
- Bacterial foodborne pathogens do not grow on the surface of peels
- Some risk of fungal growth and possibility of mycotoxin production
- If banana looks or smells moldy, it should be discarded
- Bananas that do not look or smell moldy can be safely consumed

Bread

- Literature on mycotoxin formation in breads is limited and conflicting
- Most reports indicate that mycotoxins formed on bread products inoculated with mycotoxigenic strains
 - Most say little diffusion away from fungal hyphae.
 - Others report mycotoxin diffusion away from hyphae
- Bread with extensive mold should be discarded
- Bread with few mold colonies can be salvaged
- If the mold has penetrated the loaf, it should be discarded

Fig. 2. Growth of *Aspergillus flavus* strain No. 373 on bread and distribution of aflatoxins after 6 days at 30°C.

Modeling

Copyright ©, International Association for Food Protection

Modeling the Growth of *Salmonella* in Raw Poultry Stored under Aerobic Conditions

SILVIA A. DOMINGUEZ AND DONALD W. SCHAFFNER*

School of Biological and Environmental Sciences, Rutgers, The State University of New Jersey, Food Science Department, 65 Dudley Road, New Brunswick, New Jersey 08901-8520, USA

MS 08-197: Received 26 April 2008/Accepted 25 July 2008

Model choice matters

Fig. 8. Graphic comparison of selected *Pseudomonas* spp. growth models.

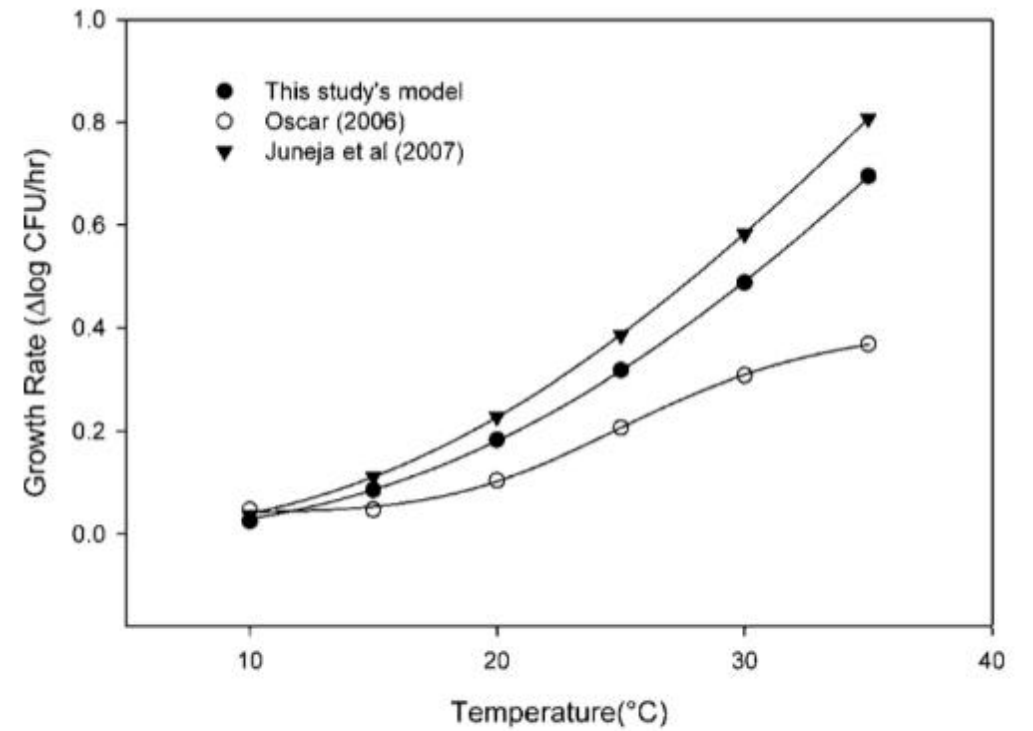

FIGURE 3. Predicted growth rates by the models of Juneja et al. (15) and Oscar (29) and the model developed in this study.

Temperature matters

Table 4
Predicted raw poultry shelf-life at different storage temperatures

Storage temperature (°C/°F)	Predicted growth rate (ΔlogCFU/h)	Predicted shelf-life ^a
0/32	0.01	17 days
4.4/40	0.04	6 days
10/50	0.09	2 days
25/77	0.34	15 h

^a End of shelf-life=time to reach 10⁷ CFU/cm². Based on experimental data, an initial concentration of 10² CFU/cm² is assumed.

- ~ 3x faster at 10 °C
- ~ same at 25 °C

TABLE 4. Predicted and experimental antibiotic-resistant and nonresistant *Salmonella* (initial population ≤10 CFU/cm²) growth rates on raw poultry at temperatures of 10 to 35°C

Temp (°C)	<i>Salmonella</i> growth rate (Δlog CFU/h)		
	Predicted	Experimental	
		Antibiotic-resistant	Non-antibiotic-resistant
10	0.0252	0.0147	ND ^a
15	0.0862	0.0457	0.0364
20	0.1837	0.1059	0.1102
25	0.3177	0.1584	0.0957
30	0.4880	0.5955	0.3118
35	0.6949	1.0130	1.4950

^a ND, not determined. *Salmonella* growth could not be determined at 10°C because of high interference from non-*Salmonella* organisms able to grow on XLT4 media.

Initial conditions matter

- Jameson effect

Mellefont, McMeekin, and Ross (2008) Effect of relative inoculum concentration on *L. monocytogenes* growth in co-culture. IJFM 121: 157–168

152

L.A. Mellefont et al. / International Journal of Food Microbiology 121 (2008) 157–168

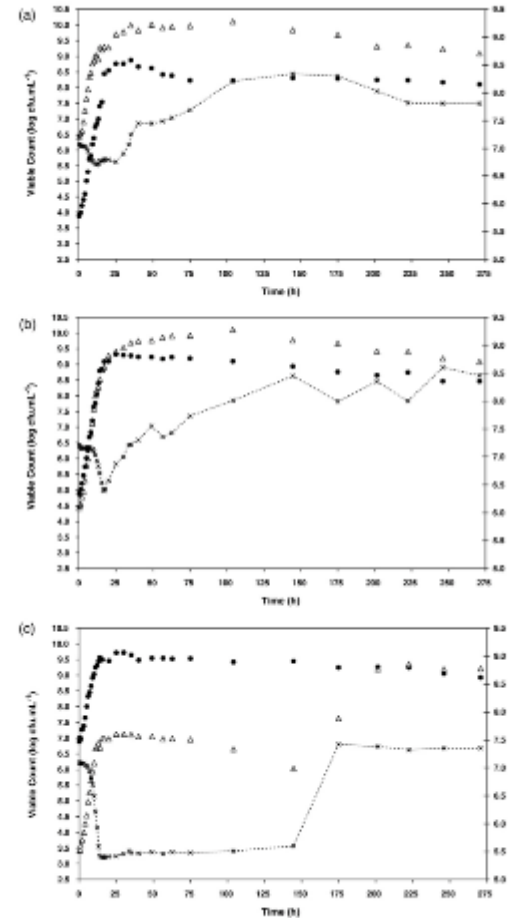

Fig. 2. Growth of *L. monocytogenes* (●) in co-culture with *P. fluorescens* (△) at 25 °C with (a) high starting numbers (10^7 cfu mL $^{-1}$) of *P. fluorescens* and low starting numbers (10^5 cfu mL $^{-1}$) of *L. monocytogenes*, (b) equal starting numbers (10^6 cfu mL $^{-1}$) of both strains and (c) high starting numbers (10^7 cfu mL $^{-1}$) of *L. monocytogenes* and low starting numbers (10^5 cfu mL $^{-1}$) of *P. fluorescens*. pH (—) is also provided.

- Equal
- Lower

Questions?

1. Understanding food loss and how it affects food security/sustainability.

Real-world Solutions to a Global Issue

The world wastes vast amounts of food.

33%

of all food produced globally, goes to waste*.¹

* In certain regions this figure is as high as 50%.²

At a time when **sustainable food systems** are a **global imperative**, food preservation has a crucial role to play.

Financially, socially and environmentally.

Kerry's Food Protection and Preservation business can help you to:

- Extend shelf life
- Protect margins
- Inspire consumer confidence

¹ FAO, Global Food Losses and Waste
² Michigan State University, Americans Waste Almost 50 Percent of Food Produced

Where Protecting Food Can Make an Impact

Shelf-life confidence

68%

of consumers say the use by or best before date is the number one indicator for them of **food safety**.¹

Unlocking value

Over **52 billion**

servings of meat were preserved and protected by Kerry ingredients in 2022.⁵

Less waste

66%

of consumers say they want to cut waste.³

Yet up to half of global food waste occurs at consumer level.²

Our consumer surveys show that extra shelf-life days and education make a big impact on waste

Low sodium

Low/no/reduced sodium was in the **top 3 positions** across all regions in 2022.⁴

Replacing sodium-based preservatives can help without compromising on shelf life.

More time

A customer saw a **25%**

waste reduction by switching from HPP to an ingredient-based clean label solution.

Shelf-life protection after opening is a big weakness in clean label products.⁵

¹ Kerry, Food Safety Fundamentals 2021

² FAO, Food loss and waste

³ FMCG Gurus Sustainability & Clean Label Trends 2021

⁴ Innova Market Research, 2022

⁵ Kerry Proprietary Information

Food safety: facts, stats, trends & insights

Recalls: the unpalatable price

\$10M

is the average cost of a product recall. It is this industry's biggest threat to profitability and does not include brand damage and lost sales.¹

Safety = the date

68%

of consumers use shelf-life dates as a key indicator of safe food.²

Spoilage alerts

49%

of consumers have raised safety worries concerning spoilage issues for the refrigerated plant-based meat industry. Consumers often mistake signs of spoilage (sight, smell, taste) with food safety.²

Contaminations: a major issue

45%

of USDA recalls in 2022 were due to contamination, which is still a leading cause of recalls globally.³

¹ Joint industry study by the Food Marketing Institute and the Grocery Manufacturers Association

² Kerry, Food Safety Fundamentals 2021

³ USDA and Kerry global market analysis

Clean Label Trends & Insights

63%

of consumers prefer natural preservatives in their food and beverages (vs. 5% artificial and 25% both).¹

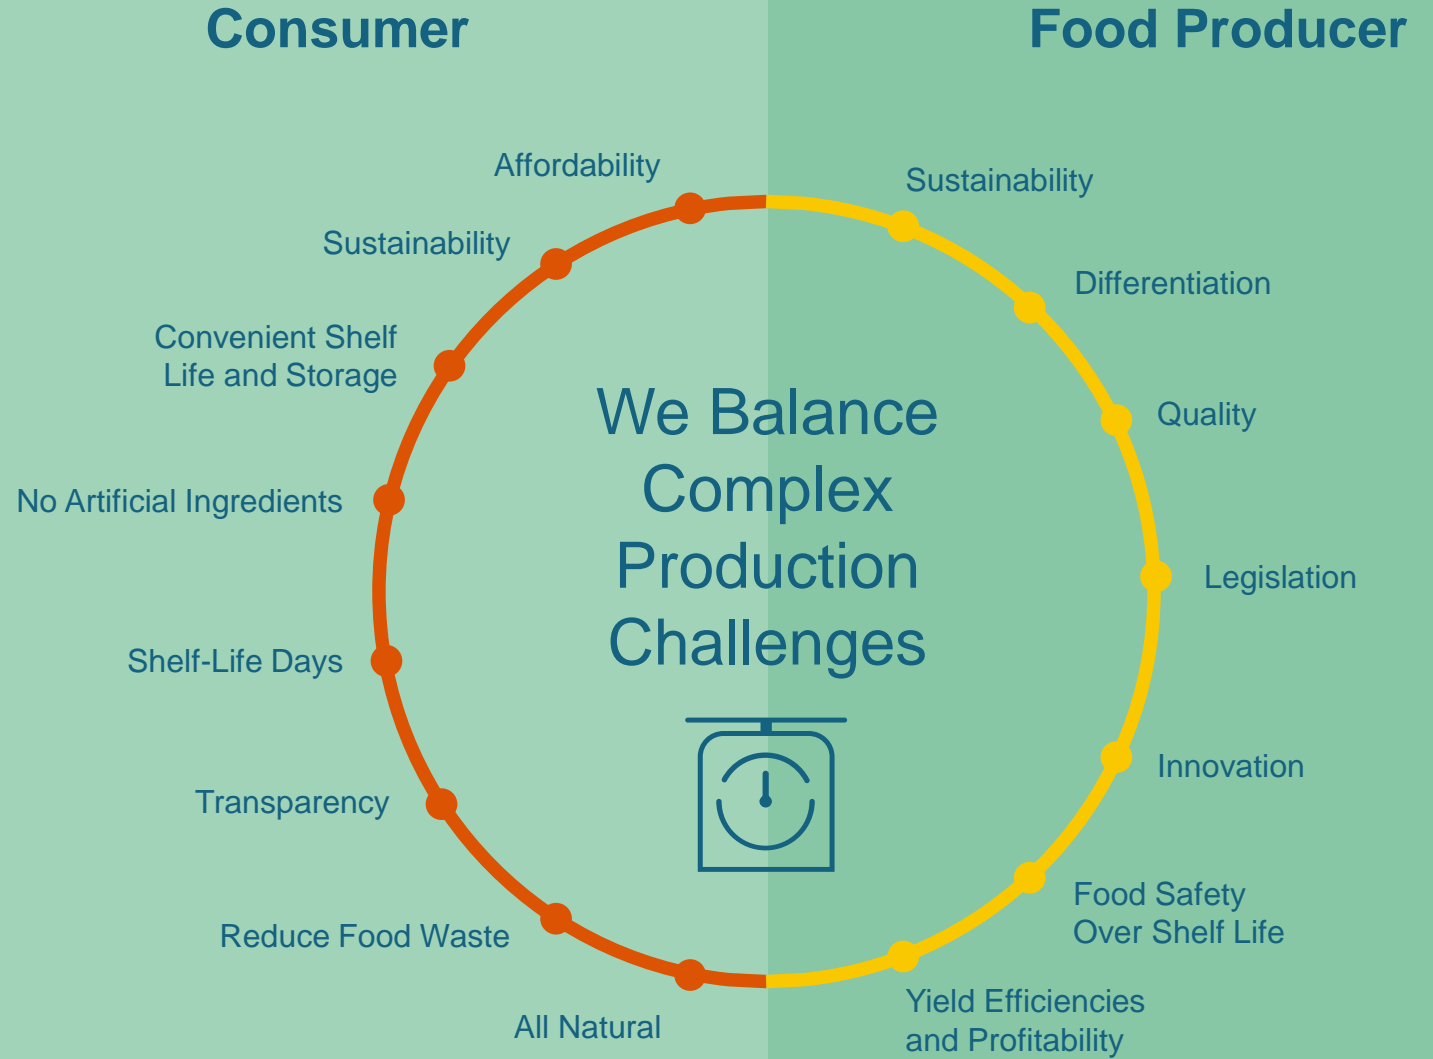

60%

of consumers say the ingredients list/declarations are their top purchase driver.²

¹ Kerry, North America Food Safety Fundamentals, 2021
² Kerry, Sustainability in Motion, 2021

Consumer's Needs. Producer's Needs.

2. Microbial ecology and physiology of common spoilage culprits.

Microbial presence in food products

Cleaning reduces initial load

Not completely sterile → products exposed to microbes

A bacteriostatic component is needed for control !

“Everything is everywhere and the environment selects”

M.W. Beijerinck 1913

Role of Microorganisms in Food

- The foods we eat, irrespective of how they are prepared, are seldom sterile.
- Most foods are 'naturally' contaminated with spoilage microorganisms and occasionally with pathogens.

THE GOOD THE BAD AND THE UGLY

Fermentation
Biopreservation

Pathogens

Spoilage
organisms

Spoilage

“Spoilage is any change that renders a product unacceptable for human consumption” (Hayes, 1985).

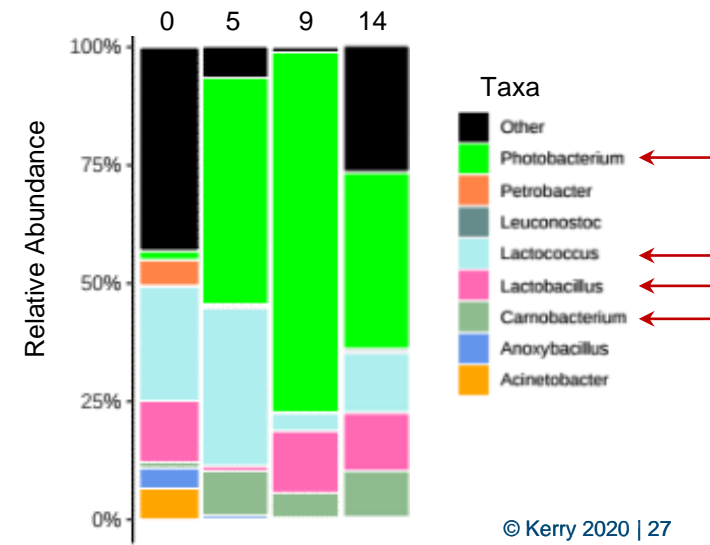

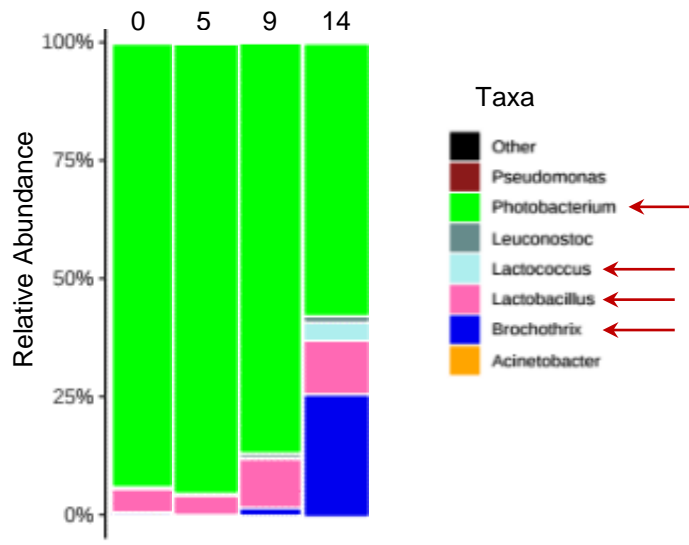

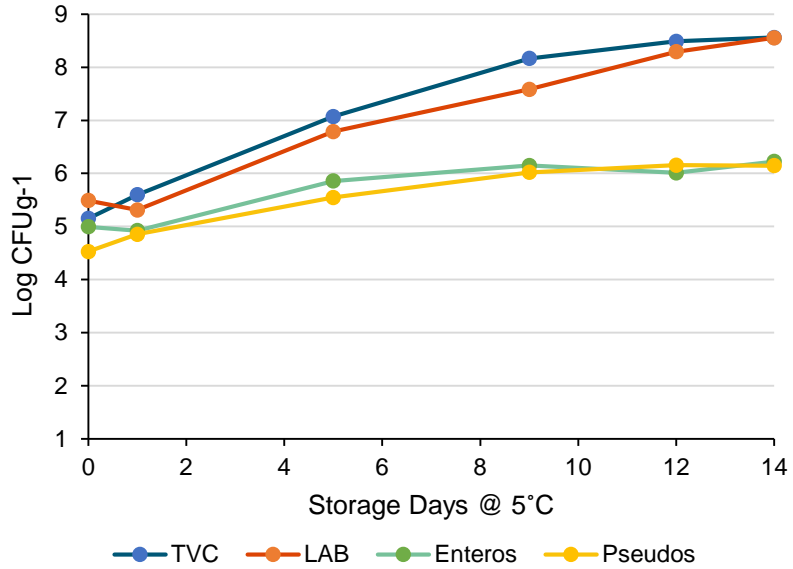

SHELF-LIFE is the period of storage until spoilage.

- **Physical** (package failure, purge)
- **Chemical/enzymatic** (proteolysis, lipolysis)
- **Microbial** (bacteria, yeast, mould)

Consumer Defines Spoilage

- sensitivity
- cultural background
- economic considerations

Microflora of Minced Beef, Pork and Chicken

Burden of Foodborne Illness- US

Pathogens causing the most foodborne illnesses, hospitalizations, and deaths each year

Top five pathogens contributing to domestically acquired foodborne illnesses

Pathogen	Estimated number of illness	90% credible interval	%
Norovirus	5,461,731	3,227,078-8,309,480	58
Salmonella, nontyphoidal	1,027,561	644,786-1,679,667	11
Clostridium perfringens	965,958	192,316-2,483,309	10
Campylobacter spp	845,024	337,031-1,611,083	9
Staphylococcus aureus	241,148	72,341-529,417	3
subtotal			91

Listeria monocytogenes facts

- *Listeria monocytogenes* are widely distributed in nature. They can be found in soil, water, vegetation and the faeces of some animals and can contaminate foods.
- High risk foods include deli meat and ready-to-eat products soft cheeses and cold smoked fishery products.
- Vulnerable group (young, old, pregnant, immuno-compromised) should avoid high risk foods.
- Invasive listeriosis is a serious disease with 20-30% mortality rate

58 recalls for a variety of foods in 2020

Every year, about 1,600 people get listeriosis in the USA

3. Potential solutions to the challenge of food spoilage.

Ingredients to Achieve Food Safety and Reduce Waste

Multiple pillars come together as:

Multifunctional Systems

Combined technologies / products to meet specific goals. Demonstrated efficacy at low inclusion levels.

Leistner Hurdle Concept

Hurdle Technology is the combined use of several preservation methods to improve the safety & quality of a product.

Microorganism won't be able to 'adapt' to all the hurdles.

Leistner 1978

The Market Has Historically Relied on Antimicrobials Derived from Different Supply Chains to Address Conventional & Clean Label Needs

Complexity Impact =
Different formulation considerations, different supply chains, fewer economies of scale, etc.

Lactate/Diacetate Based
Conventional Preservation

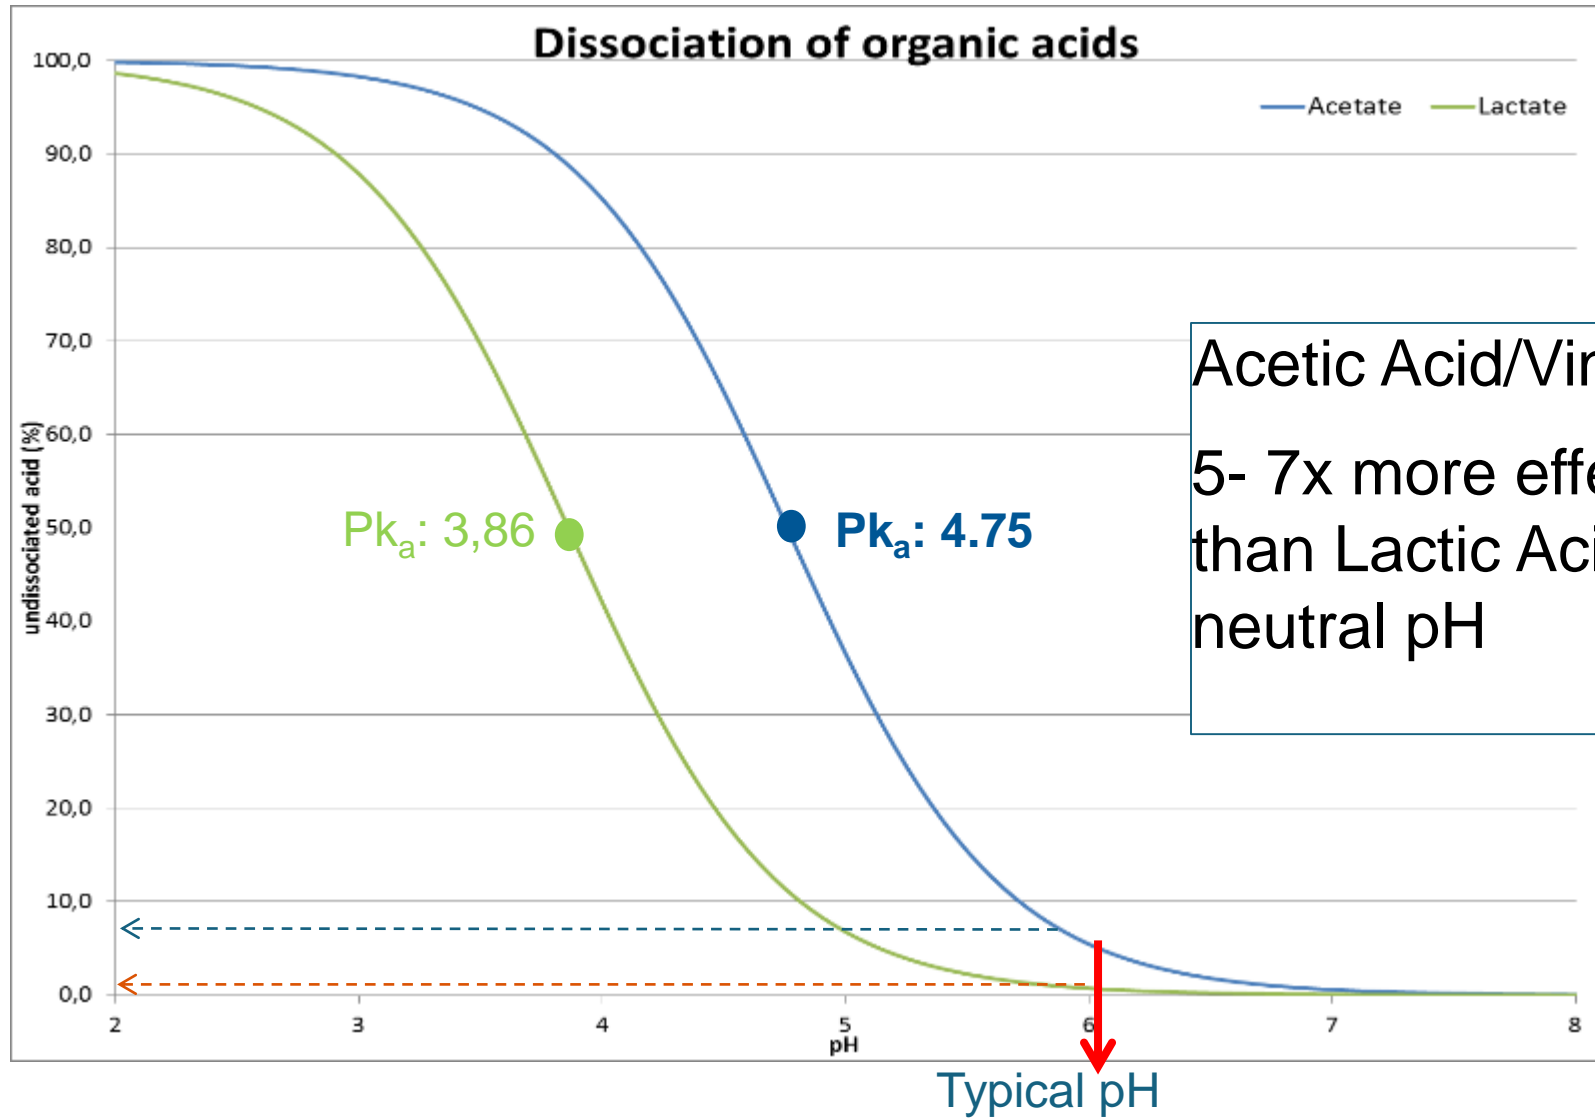

Vinegar (Acetate)-Based
Clean Label Preservation

AM working mechanism of organic acids

- Undissociated acid is the effective
- Acetic acid has relative high pKA
- Basic chemistry → rel. high amount of undissociated at neutral pH

4. The power of Predictive modeling

Food Spoilage and Safety Predictor (FSSP)

The FSSP software is distributed free of charge from:
<http://fssp.food.dtu.dk>

Predictive modeling

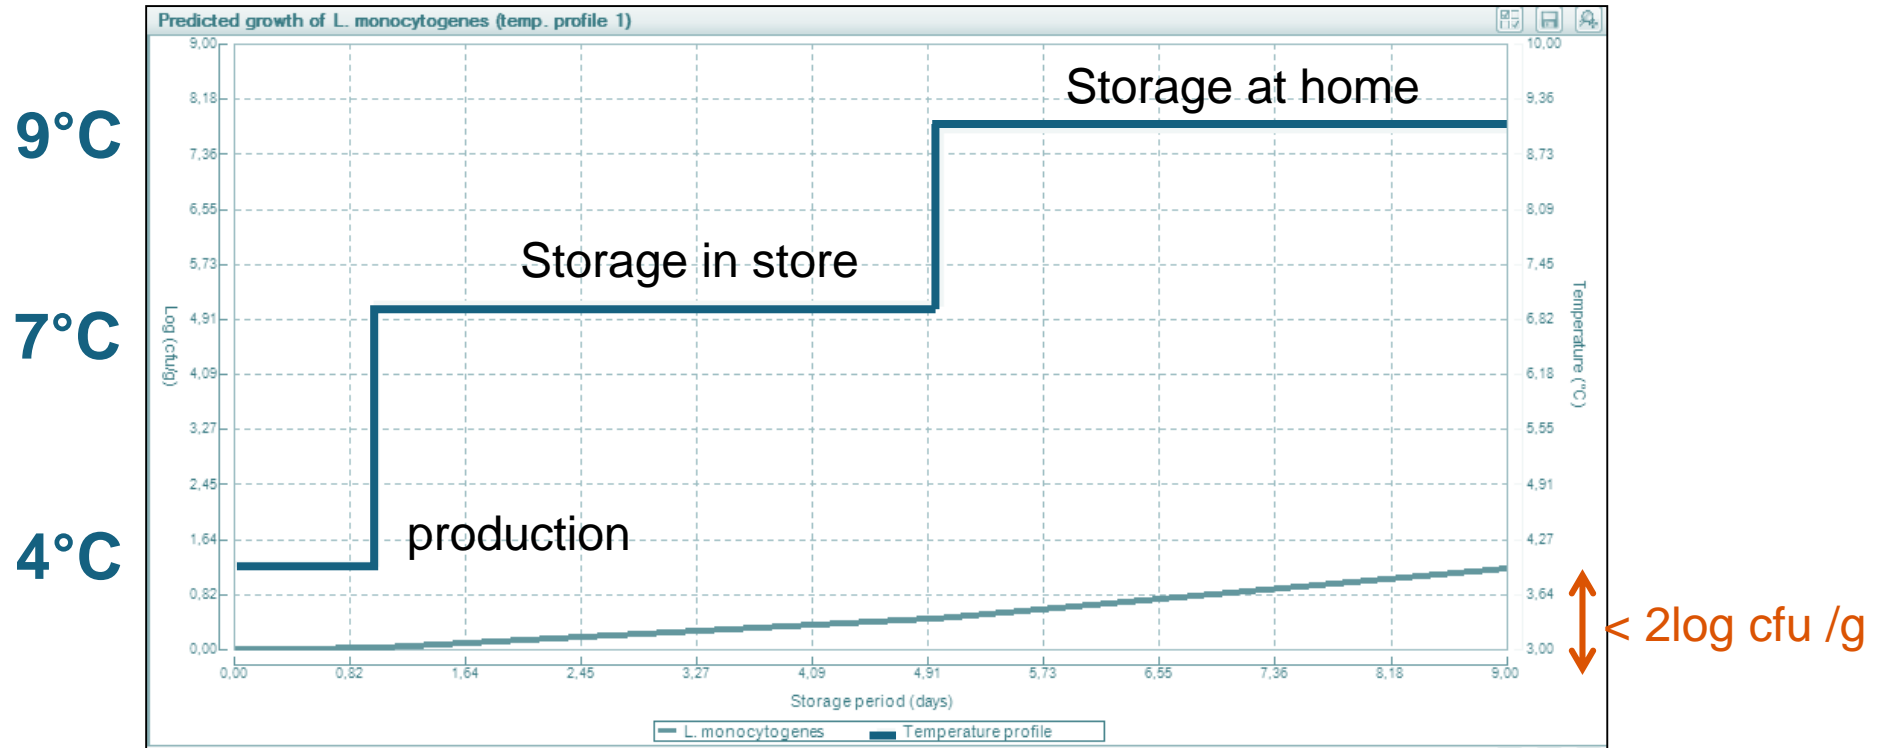

Predict the growth of organisms causing spoilage or food borne illness based on food and storage parameters

- Direct insight on spoilage thresholds
- Direct insight on safety control of food products
- Reduces time and money spend with challenge studies (accepted at food authorities!!)

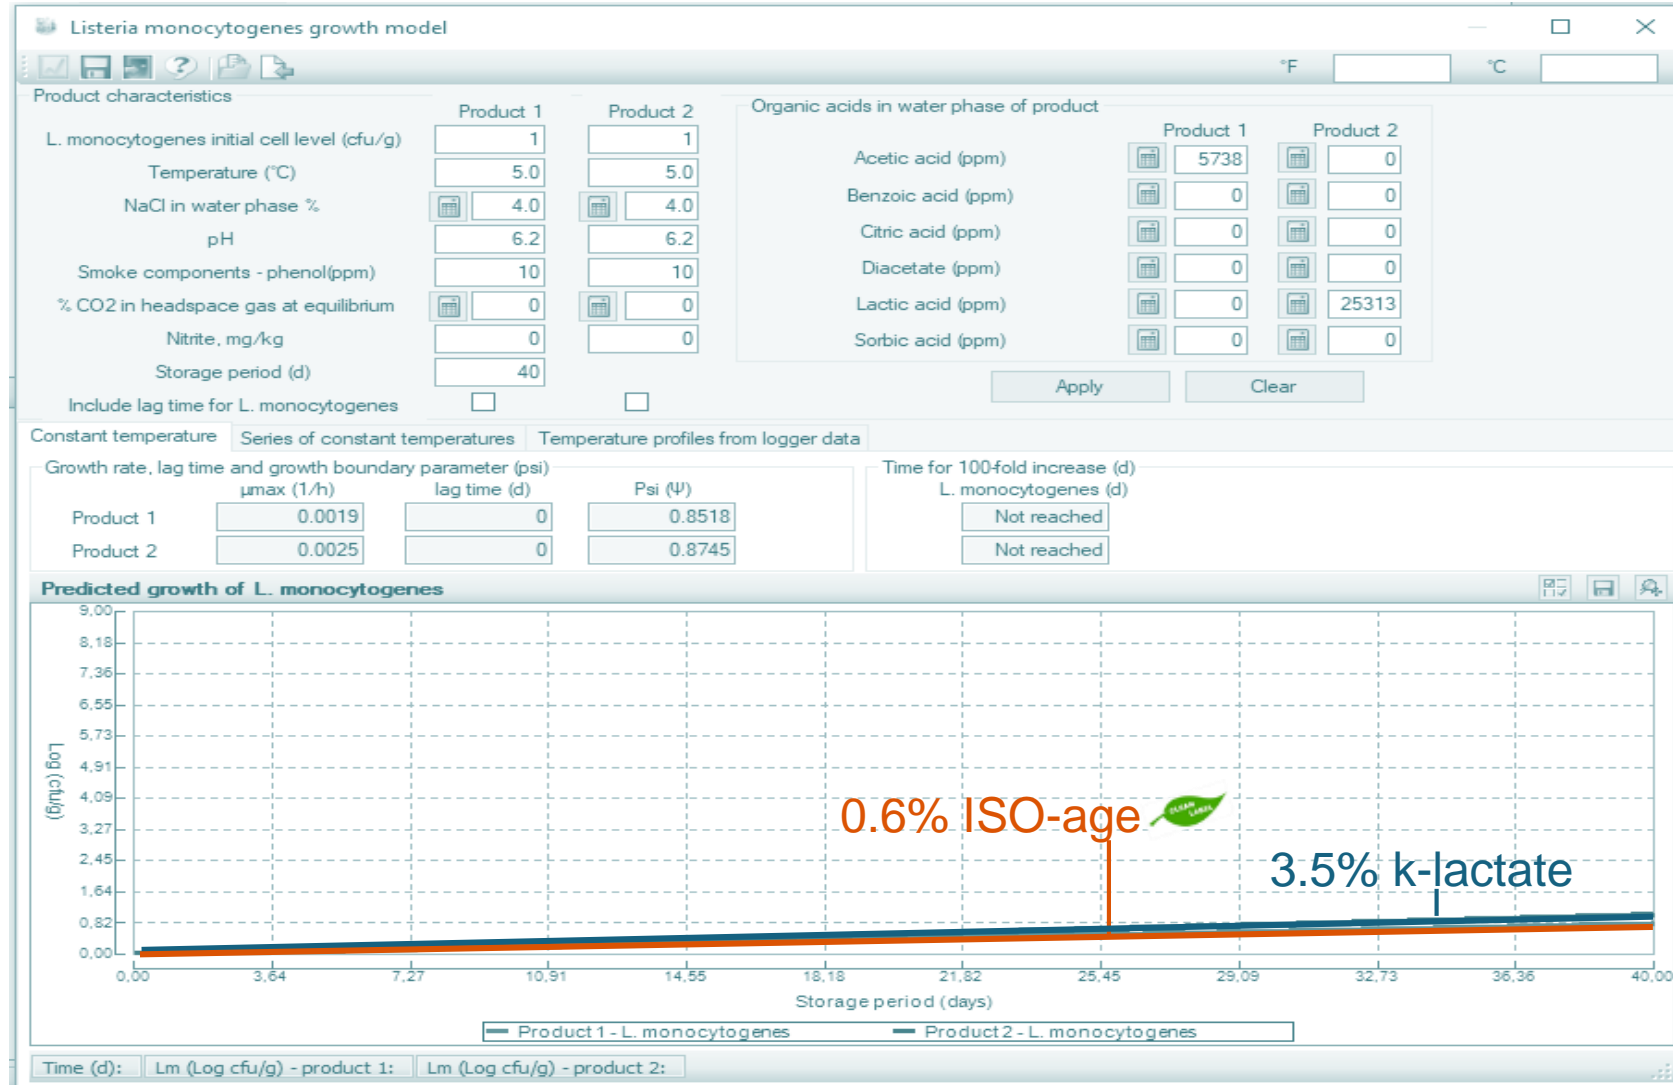

Saves time and money!

Predicted *Listeria* growth

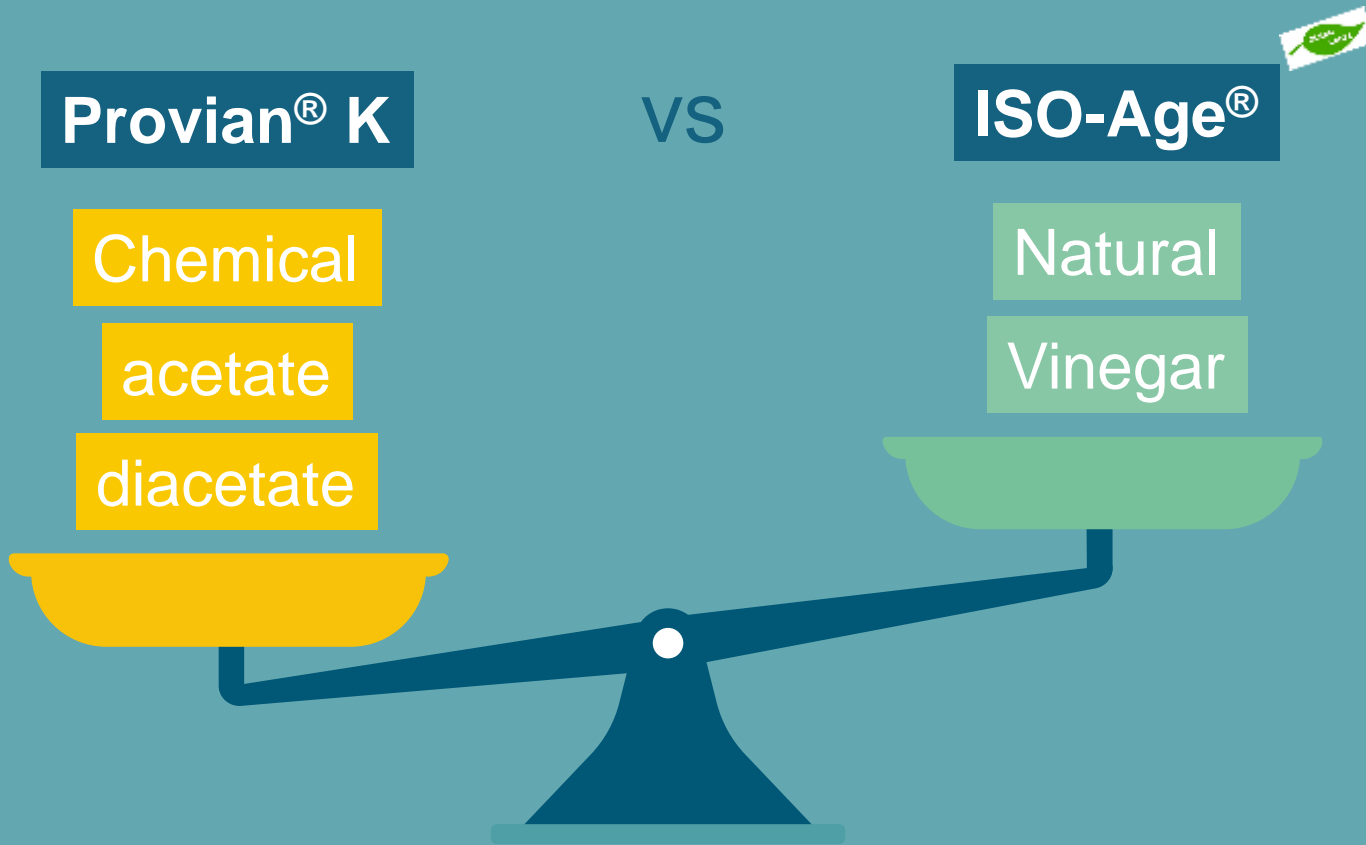

Vinegar (Acetate) vs. Lactate

5. Experimental data

Objective: Chemical vs Natural

Treatments:

- **Control (no antimicrobials)**
- **0.5% Provian K**
- **0.5% ISO-Age** 
- **0.65% ISO-Age** 

Microbial Analysis

Triplicate inoculated samples of each treatment were assayed

Rinsed meat in 100ml of Butterfield's phosphate buffer and hand massaged externally for 3 minutes

Enumerated on Modified Oxford agar (MOX, 35°C, 48h) for populations *L.monocytogenes*.

Background flora measured on PCA and APT + bromocresol purple.

Results

Proximate analysis

All treatments were tested

Moisture: 71.1% - 73.4%

pH: 6.21 - 6.42, constant over time

% NaCl: 1.82 - 2.10

Background flora

(PCA & APT+ bromocresol) <1 log cfu/g

Efficacy in cooked ham at 4°C

Listeria monocytogenes in cooked ham (+4°C)

Efficacy in cooked ham at 7°C

Listeria monocytogenes in cooked ham (+7°C)

Conclusions

- Vinegars and acetates are highly effective at meat pH due to high pK value
- comparable antimicrobial efficacy of chemical and natural (vinegar based) Acetates
- Theory and model predictions are confirmed by experimental validation.

What happens when we eliminate sources of food waste?

See the impact you could have on the planet's resources [here](#)

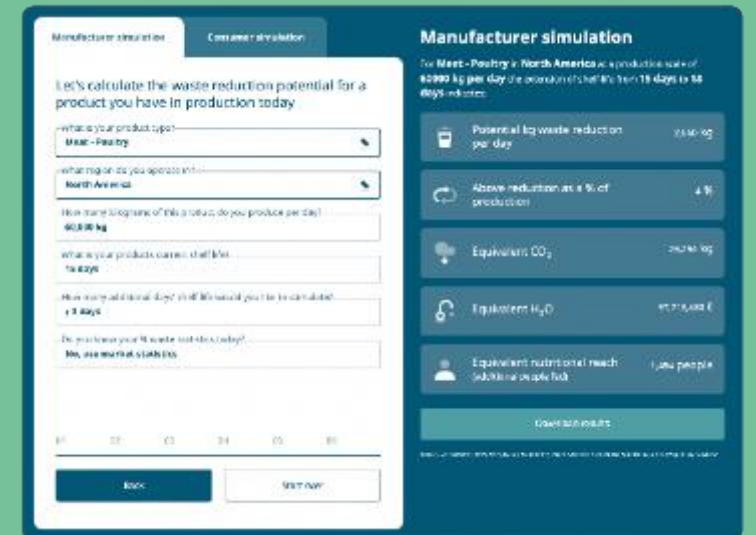

Whether you're a food manufacturer or a concerned citizen – or both – access our Food Waste Estimator.

Input some production information, and the Estimator will give an instant guide to the impact that you could achieve.

With food and energy prices at an all-time high, and climate change at critical levels, **now is the time.**

Disclaimer: The results of the food waste estimator are indicative and not designed to represent a quantitative measure of a customer's/consumer's sustainability impact. The outputs should not inform front of pack claims or sustainability claims.

More Shelf Life = Less Waste

Manufacturer simulation | Consumer simulation

Let's calculate the waste reduction potential for a product you have in production today

What is your product type?
Bread

What region do you operate in?
Europe

How much of this product do you produce?
20,000 kg per day

What is your products current shelf life?
7 days

How many additional days' shelf life would you like to stimulate?
+ 3 days

Do you know your % waste statistics today?
No, use market statistics

01 02 03 04 05 06

Back Start over

Manufacturer simulation

For **Bread** in **Europe** at a production scale of **20,000 kg per day** the extension of shelf-life from **7 days** to **10 days** indicates:

Potential volume waste reduction	2,232 kg per day
Above reduction as a % of production	11 %
Equivalent CO ₂	4,812 kg
Equivalent H ₂ O	539,943 l
Equivalent nutritional reach (additional people fed)	1,253 people fed for one day

Download results
